1 Automata theory

1.1 Lecture 1

Definition 1.1.1.

1. An *alphabet* is a nonempty finite set of characters, e.g., $\Sigma := \{0, 1\}$.
2. A *string* is a finite ordered sequence of elements from a given alphabet Σ .

The empty sequence ϵ is allowed.

Let Σ^* denote the set of all finite-length strings over Σ . Any subset of Σ^* is called a (*formal*) *language*.

We can define a total order called the *string order* on Σ^* by extending the lexicographic order on the set of all strings over Σ of length n so that any string of length n_1 is strictly less than any string of length n_2 whenever $n_1 < n_2$.

Example 1.1.2. Both the set of binary strings representing prime numbers and the set of binary strings with an even number of 1's are languages.

Consider a function $f : \{0, 1\}^* \rightarrow \{0, 1\}$. The computation of f is equivalent to determining whether

$$x \in \underbrace{f^{-1}(1)}_{\text{a language}} \subset \{0, 1\}^* .$$

Thus, computing a Boolean function is the same as determining membership in some language.

Informally, finite automata are characterized by $O(1)$ memory and passing over their inputs exactly once. Formally, an *m-state deterministic finite automaton* (DFA) is a 5-tuple

$$M := (Q, \Sigma, q_0, \delta, Q_F) \tag{\alpha}$$

where $|Q| = m$, Σ is an alphabet, $q_0 \in Q$, $\delta : Q \times \Sigma \rightarrow Q$, and $Q_F \subset Q$. We call δ the *transition function* of M .

In other words, an automaton M is a DFA if

- (a) M has a finite number of states Q ,
- (b) M has a unique *starting state* q_0 ,
- (c) for every state q and every symbol $\sigma \in \Sigma$, there is a unique next state $\delta(q, \sigma)$,
- (d) M 's computation begins at q_0 and applies δ in order, and
- (e) certain states Q_F are designated as *final states*.

Aside. For each alphabet Σ , we have a category \mathbf{Aut}_Σ whose objects are precisely DFA's in Σ and whose morphisms $(Q, \Sigma, q_0, \delta, Q_F) \rightarrow (Q', \Sigma, q'_0, \delta', Q'_F)$, called *simulations*, are precisely functions $f : Q_M \rightarrow Q_N$ such that

- (i) $f(q_0) = q'_0$,

(ii) $f(\delta(q, \sigma)) = \delta'(f(q), \sigma)$, and

(iii) $f(Q_F) \subset Q'_F$.

Consider $x := x_1x_2 \cdots x_n \in \Sigma^*$. Let $q_0(x) = q_0$, and for each $1 \leq i \leq n$, let

$$q_i(x) = \delta(q_{i-1}(x), x_i).$$

If $x = \epsilon$, then $n = 0$, from which we recover the equation $q_0(x) = q_0$. We say that x is *accepted by M* if $q_n(x) \in Q_F$.

Notation. $L(M) := \{x \in \Sigma^* : M \text{ accepts } x\}$.

Example 1.1.3. Set $\Sigma = \{0, 1\}$.

1. Let M denote

Then $L(M)$ consists of all binary strings with an even number of 0's.

2. Let M denote

Then $L(M) = \{x \in \Sigma^* : x = y101z \text{ for some strings } y \text{ and } z\}$.

Definition 1.1.4 (Regular language). A language L is *regular* if there is some DFA M such that $L(M) = L$.

Definition 1.1.5 (Regular expression). A *regular expression* over Σ is defined recursively as either

- the symbol \emptyset ,
- the symbol ϵ ,
- a symbol $a \in \Sigma$,
- the symbol $\underbrace{(R_1 \cup R_2)}_{R_i \text{ regular}}$,
- the symbol $\underbrace{(R_1 \circ R_2)}_{R_i \text{ regular}}$, or
- the symbol (R^*) , R regular.

As it turns out, every regular expression generates a DFA (i.e., a regular language), and vice versa. Thus, they have equal expressive power. The former specifies rules for generating legitimate strings, whereas the latter recognizes membership of a language.

Definition 1.1.6. A *nondeterministic finite automaton* (NFA) is a quintuple $(Q, \Sigma, q_0, \delta, Q_F)$ of the sort (α) except that $\delta : Q \times \Sigma \rightarrow \mathcal{P}(Q)$.

Example 1.1.7. Set $\Sigma = \{0, 1\}$ and $M =$

If $x = 0100$, then

$$\begin{aligned} q_0(x) &= \{q_0\} \\ q_1(x) &= \{q_0\} \\ q_2(x) &= \{q_0, q_1\} \\ q_3(x) &= \{q_0, q_2\} \\ q_4(x) &= \{q_0, q_2\}. \end{aligned}$$

1.2 Lecture 2

Let δ denote a transition function for the NFA N . Define the *multi-step transition function*

$$\hat{\delta} : Q \times \Sigma^* \rightarrow \mathcal{P}(Q)$$

inductively by

$$\begin{aligned} \hat{\delta}(q, \epsilon) &= \{q\} \\ \hat{\delta}(q, x) &= \bigcup_{\gamma \in \hat{\delta}(q, y)} \delta(\gamma, \sigma) \quad x = y\sigma, y \in \Sigma^*, \sigma \in \Sigma. \end{aligned}$$

Note that if $p \in \hat{\delta}(q, y)$ and $r \in \hat{\delta}(p, \sigma)$, then $r \in \hat{\delta}(q, y\sigma) = \hat{\delta}(q, x)$.

Definition 1.2.1. A string x is *accepted by N* if $\hat{\delta}(q_0, x) \cap Q_F \neq \emptyset$

Notation. $L(N) := \{x \in \Sigma^* : N \text{ accepts } x\}$.

Every DFA is an NFA, in which case we have that $\hat{\delta}(q, x) = \left\{ \delta \left(\hat{\delta}(q, y), \sigma \right) \right\}$. It's not the case, however, that any NFA is a DFA.

Theorem 1.2.2. *For any NFA N , there is some DFA M such that $L(N) = L(M)$.*

Proof. Let $N = (Q, \Sigma, q_0, \delta_N, Q_F)$. Define the DFA

$$M := \left(\mathcal{P}(Q), \Sigma, q_0^{(1)}, \delta_M, Q_F^{(1)} \right)$$

by

$$q_0^{(1)} = \{q_0\}, \delta_M(Q', \sigma) = \bigcup_{\gamma \in Q'} \delta_N(\gamma, \sigma), Q_F^{(1)} = \{R \subset Q : R \cap Q_F \neq \emptyset\}.$$

For any string x , one can use induction on $|x|$ to show that if $R \subset Q$, then

$$\tilde{\delta}_M(R, x) = \bigcup_{p \in R} \hat{\delta}_N(p, x)$$

where $\tilde{\delta}_M : \mathcal{P}(Q) \times \Sigma^* \rightarrow \mathcal{P}(Q)$ denotes the obvious extension of δ_M to all strings. Now just take $R \equiv \{q_0\}$. □

Example 1.2.3. Let $L \subset \{0, 1\}^*$ consist of those strings x such that “1010” appears in x . We can easily capture L with the following NFA, but writing a DFA that captures L is much harder.

Definition 1.2.4.

1. An NFA is called an ϵ -NFA if its transition function is of the form $\delta : Q \times (\Sigma \cup \{\epsilon\}) \rightarrow \mathcal{P}(Q)$. In this case, we call δ an ϵ -transition.
2. Let q be a state. The ϵ -closure of q is the set of states that can be reached from q by taking finitely many ϵ -transitions.

This determines a function $\epsilon\text{-cl}(-) : \mathcal{P}(Q) \rightarrow \mathcal{P}(Q)$.

Note 1.2.5. We have that $\hat{\delta}(q, x) = \begin{cases} \epsilon\text{-cl}(q) & x = \epsilon \\ \bigcup_{r \in \hat{\delta}(q, y)} \epsilon\text{-cl}(\delta(r, \sigma)) & x = y\sigma \end{cases}$.

Theorem 1.2.6. For any ϵ -NFA N , there is some DFA M such that $L(N) = L(M)$.

Proof. Use a similar argument to the proof of Theorem 1.2.2. In particular, take

$$q_0^{(1)} \equiv \epsilon\text{-cl}(q_0)$$

$$\begin{aligned} \delta_M(R, \sigma) &\equiv \bigcup_{r \in R} \bigcup_{p \in \epsilon\text{-cl}(r)} \bigcup_{s \in \delta_N(p, \sigma)} \epsilon\text{-cl}(s) \\ &= \bigcup_{r \in R} \bigcup_{s \in \delta_N(r, \sigma)} \epsilon\text{-cl}(s). \end{aligned}$$

□

1.3 Lecture 3

Proposition 1.3.1. Let $L_1, L_2 \subset \Sigma^*$ be regular.

- (a) $\overline{L_1} := \Sigma^* \setminus L_1 = (L_1)^c$ is regular.

Corollary 1.3.2. *If L is finite or cofinite, then it is regular.*

- (b) $L_1 \cup L_2$ is regular.
- (c) $L_1 \cap L_2$ is regular.
- (d) The language $L_1 \cdot L_2 \equiv \{xy \mid x \in L_1 \wedge y \in L_2\}$ is regular.

Proof. By assumption, there exist DFA's M_1 and M_2 such that $L_1 = L(M_1)$ and $L_2 = L(M_2)$.

- (a) Construct a new DFA M_3 by making every final state of M_1 non-final and vice versa. Then $L(M_3) = \overline{L_1}$.
- (b) Construct an ϵ -NFA M_3 as follows. Take a starting state q_0 . Attach an ϵ -transition from q_0 to the starting state of M_1 and an ϵ -transition from q_0 to the starting state of M_2 . Then $L(M_3) = L_1 \cup L_2$.
- (c) Note that $L_1 \cap L_2 = (\overline{L_1} \cup \overline{L_2})^c$. Now apply parts (a) and (b).
- (d) Construct an ϵ -NFA M_3 as follows. Given any final state q of M_1 , add an ϵ -transition from q to the start state of M_2 . Then $L(M_3) = L_1 \cdot L_2$.

□

Now, let L be any language. Let $L^k := \underbrace{L \cdot L \cdots L}_{k \text{ times}}$ for each integer $k \geq 1$. Moreover, let $L^0 = \{\epsilon\}$ (which is regular). Then let

$$L^* = \bigcup_{k \geq 0} L^k.$$

Proposition 1.3.3. *If L is regular, then L^* is regular as well.*

Proof. There is some DFA M such that $L(M) = L$. Without loss of generality, write M as

Now, let \tilde{M} denote the automaton

Then $L(\tilde{M}) = L^*$.

□

There exist bijections $\{0, 1\}^* \xrightarrow{\cong} \mathbb{N}$ and $\{F : F \text{ is a finite automaton}\} \xrightarrow{\cong} \mathbb{N}$. In particular, this means that

$$\mathbb{R} \cong \mathcal{P}(\mathbb{N}) \cong \mathcal{P}(\{0, 1\}^*) = \{L : L \text{ is a language over } \{0, 1\}\}.$$

Since we have a surjection

$$\{F : F \text{ is a finite automaton}\} \rightarrow \{L : L \text{ is a regular language over } \{0, 1\}\},$$

it follows that there are uncountably many non-regular languages over $\{0, 1\}$.

1.4 Lecture 4

Lemma 1.4.1 (Pumping). *Let L be a regular language. Then there exists $n_0 \in \mathbb{N}$ such that for any $x \in L$ with $|x| \geq n_0$, we may write $x = wyz$ such that*

(a) $|y| > 0$,

(b) $|wy| \leq n_0$, and

(c) if $i \geq 0$, then $wy^iz \in L$ where $y^i := \underbrace{y \cdots y}_{i \text{ copies}}$.

Terminology. In this case, we call the minimal such n_0 the *pumping length* of L .

Proof. By assumption, there is some DFA $M = (Q, \Sigma, \delta, q_0, Q_F)$ such that $L = L(M)$. Let $n_0 = |Q|$. Let $x \in L$ such that $|x| \geq n_0$. Set $q_i = \hat{\delta}(q_0, x_0 \cdots x_i)$ for each $i \geq 0$. There exist $0 \leq i < j \leq n_0$ such that $q_i = q_j$. Consider the three strings

$$w := x_1 \cdots x_i$$

$$y := x_{i+1} \cdots x_j$$

$$z := x_{j+1} \cdots x_m.$$

where $|x| = m$. It is straightforward to verify that these satisfy conditions (a), (b), and (c). \square

Corollary 1.4.2.

1. Any regular language L has pumping length $\leq |Q|$.
2. If $L(M) \neq \emptyset$, then there exists $x \in L(M)$ such that $|x| \leq |Q|$.

Example 1.4.3. Let $n_0 \geq 0$ be an integer. Suppose that $x = wyz$ with $|y| > 0$ and $|wy| \leq n_0$.

1. Let $L = \{1^{2^n} : n \geq 0\}$ and $x = 1^{2^{n_0+1}}$. Note that

$$|wy^iz| = |wyz| + (i-1)|y| = 2^{n_0+1} + (i-1)|y|.$$

Hence if $i = 2$, then

$$|wy^iz| = 2^{n_0+1} + |y| \leq 2^{n_0+1} + n_0 < 2^{n_0+2}$$

since $n_0 < 2^{n_0+1}$, in which case $2^{n_0+1} < |wy^iz|$ as well. Therefore, L is *not* a regular language.

2. Let $L = \{ww : w \in \{0,1\}^*\}$. Let $x = 0^{n_0}10^{n_0}1$. If $|y| = m$ with $0 < m \leq n_0$, then $wz = 0^{n_0-m}10^{n_0}1$, which does not belong to L . Hence L is *not* a regular language.

Let D be a DFA with $|Q_D| = n$. Then D recognizes an infinite language if and only if it accepts a string s such that $n \leq |s| \leq 2n$.

Indeed, the (\Leftarrow) direction follows from the pumping lemma. Conversely, suppose that $L(D)$ is infinite. Then D contains a path p of states from the start state to a final state as well as a cycle c of states that intersects p . Note that $|c| \leq n$ and $|p| \leq n$. Hence we can follow c sufficiently many times to get our desired string.

Aside. Let M be a DFA in the alphabet Σ . Consider the following two equivalence relations on Σ^* .

- Let $x \sim_M y$ if M ends at the same state on inputs x and y .
- Let $x \sim_{L(M)} y$ if $xz \in L(M) \iff yz \in L(M)$ for every $z \in \Sigma^*$.

In this case, we say that x and y are *indistinguishable* by $L(M)$.

Note that \sim_M is a *refinement* of $\sim_{L(M)}$ in the sense that every equivalence class of \sim_M is contained in an equivalence class of $\sim_{L(M)}$. This means that there are at most as many equivalence classes of $\sim_{L(M)}$ as there are of \sim_M , and thus the number of equivalence classes of $\sim_{L(M)}$ is at most $|Q_M| < \infty$.

We say that a DFA recognizing a language $L \subset \Sigma^*$ is *minimal* if it has at most as many states as any other such DFA.

Theorem 1.4.4 (Myhill-Nerode). *There exists a unique (up to isomorphism) minimal DFA recognizing $L(M)$.*

Proof. Let $M' = (Q', \Sigma, q'_0, \delta', Q'_F)$ where

- $Q' \equiv \{[x]_{\sim_{L(M)}} \mid x \in \Sigma^*\}$,
- $q'_0 \equiv [\epsilon]$,
- $\delta'([x], \sigma) \equiv [x\sigma]$, and
- $Q'_F \equiv \{[y] \mid y \in L(M)\}$.

Note that M' ends at state $[x]$ on input x , where $[x] \in Q'_F$ if and only if $x \in L(M)$. Therefore, $L(M') = L(M)$.

To see that M' is minimal, suppose that N is another DFA recognizing $L(M)$. Then the number of equivalence classes of \sim_N is at least the number of equivalence class of $\sim_{L(N)} = \sim_{L(M)}$, i.e., the cardinality of Q' . But the number of equivalence classes of \sim_N is at most $|Q_N|$. Hence $|Q_N| \geq |Q'|$, as desired.

It remains to show that M' is unique. Let $D := (Q_D, \Sigma, r_0, \delta_D, R_F)$ be another minimal DFA recognizing $L(M)$. Enumerate the states of D by q_1, \dots, q_n . For each integer $1 \leq i \leq n$, let

$$A_i = \{w \in \Sigma^* \mid \delta_D(r_0, w) = q_i\}.$$

Note that $\bigcup_{1 \leq i \leq n} A_i = \Sigma^*$. For each A_i , there exists a state $S_i \in Q'$ such that $A_i = S_i$. Then the map $D \rightarrow M'$ given by $q_i \mapsto S(i)$ is an isomorphism in \mathbf{Aut}_Σ . \square

2 Computability theory

Definition 2.0.1 (Turing machine). A *Turing machine* is a 7-tuple

$$(Q, \Sigma, \Gamma, \delta, q_0, Q_F, Q_R)$$

such that

- (i) Γ is a finite set containing Σ ,
- (ii) there is some *null character* $\perp \in \Gamma \setminus \Sigma$,
- (iii) $\delta : Q \times \Gamma \rightarrow Q \times \Gamma \times \{L, R\}$, and
- (iv) $Q_F, Q_R \subset Q$ with $Q_F \cap Q_R = \emptyset$.

We call

- Σ the *input alphabet*,
- Γ the *tape alphabet*,
- Q_F the set of *accepting states*, and
- Q_R the set of *rejecting states*.

On any given input x , a Turing machine can either *accept* or *reject* or *loop* (i.e., fail to halt on x). Such a machine is supposed to act as a minimal model of computation. It should be able to write, be able to move left and right, and have unconstrained memory.

2.1 Lecture 5

Every finite automaton may be viewed as a Turing machine M with the following properties.

- (a) M never writes on the tape.
- (b) M 's read-write head moves to the right only.
- (c) M writes on just a finite portion of the tape.
- (d) M either accepts or rejects immediately after reading the input string.

Remark 2.1.1. Adding a stay option S to the set $\{L, R\}$ would not increase a Turing machine's computational power.

Definition 2.1.2. Let M be a Turing machine. Let $q \in Q$ and $u, v \in \Gamma^*$. We say that the *configuration* of M is uqv if

- (a) the current state of M is q ,
- (b) the current tape contents is precisely uv , and
- (c) the current head location is the first symbol of v .

We call this an *accepting configuration* if $q \in Q_F$ and a *rejecting configuration* if $q \in Q_R$.

Definition 2.1.3. Let $a, b, c \in \Gamma$ and $u, v \in \Gamma^*$. Let $p, q \in Q$. We say that the configuration C_1 *yields* the configuration C_2 in the following cases.

- (a) $uapbv$ yields $uqacv$ when $\delta(p, b) = (q, c, L)$.
- (b) $uapbv$ yields $uacqv$ when $\delta(p, b) = (q, c, R)$.

In this case, we write $C_1 \vdash C_2$.

We say that the TM M *accepts* the input w if

- (i) there is some sequence C_1, \dots, C_k of configurations where C_1 is precisely $\perp q_0 w$,
- (ii) each C_i yields C_{i+1} (in which case we write $C_1 \stackrel{*}{\vdash} C_k$), and
- (iii) C_k is an accepting configuration.

We define the *language of the TM M* as

$$L(M) \equiv \{x \in \Sigma^* : M \text{ accepts } x\}.$$

Definition 2.1.4. Let L be a language.

1. We say that L is *Turing-recognizable* or *recursively enumerable* if there is some TM M such that $L = L(M)$.
2. We say that L is *decidable* or *recursive* if there is some TM M such that $L = L(M)$ and M halts on every input. In this case, we say that M is an *algorithm*.

An *enumerator* E is a Turing machine with both a work tape and an output tape (a “printer”) that begins with a blank input and possesses an additional “print” state. The language enumerated by E is precisely the set of all strings eventually printed by E . A language L is recursively enumerable if and only if an enumerator enumerates it. Indeed, the (\Leftarrow) direction is obvious. For the reverse implication, suppose that L is recognized by a Turing machine N . Enumerate Σ^* as

$$w_1 < w_2 < w_3 < \dots$$

according to the string order. Construct an enumerator E_L such that for each $i \in \mathbb{Z}_{\geq 1}$,

- (1) E_L runs N on w_1, w_2, \dots, w_i for exactly i steps and
- (2) E_L prints w_j whenever N accepts w_j .

It is easy to see that E_L enumerates L , thereby completing the (\Rightarrow) direction.

Note 2.1.5. Every decidable language is recursively enumerable.

Example 2.1.6. Using the pumping lemma, one may show that the language $L := \{0^n 1^n : n \geq 1\}$ is *not* regular. But L is decidable. Indeed, set $\Sigma = \{0, 1\}$ and $\Gamma = \Sigma \cup \{\perp, +, \times\}$. Define the TM M as follows.

Then $L(M) = L$.

Remark 2.1.7. The *Church-Turing thesis* states that our pre-theoretic notion of algorithm is entirely captured by decidability (equivalently, λ -computability).

2.2 Lecture 6

Definition 2.2.1. A *multi-tape Turing machine* is exactly like an ordinary Turing machine except that the former's transition function is of the form

$$\delta : Q \times \Gamma^k \rightarrow Q \times \Gamma^k \times \{L, R\}^k$$

where $k \in \mathbb{N}$.

Theorem 2.2.2. For any $k \in \mathbb{Z}_{\geq 1}$ and any language L , if there is some k -tape TM M such that $L(M) = L$, then there is some single-tape TM M' such that $L = L(M')$. Moreover, T steps of a k -tape TM can be simulated using $O_k(T^2)$ steps of a single-tape TM.

Proof. Write $M = (Q, \Sigma, \Gamma, \delta, q_0, Q_F, Q_R)$. Let

$$\{\#\} \cup_{\gamma \in \Gamma} \{\gamma, \dot{\gamma}\}$$

be the tape alphabet of M' . Construct M' so that its tape always has $\#$ in a cell separating the current contents of M 's different tapes and $\dot{\gamma}$ whenever the head of the tape of M containing γ is currently at γ . We make M' scan its tape once to determine the positions of the heads of M 's tapes, then scan it again to update its contents according to δ . □

Example 2.2.3. Let $L = \{w \in \{0, 1\}^* \mid w \text{ is a palindrome}\}$. This cannot be recognized by a TM running in better than quadratic time but can be recognized by a 2-tape TM running in linear time. Thus, computational models may differ in complexity even when they don't in decidability.

Definition 2.2.4. A *nondeterministic Turing machine* M is exactly like an ordinary Turing machine except that M 's transition function is of the form

$$\delta : Q \times \Gamma \rightarrow \mathcal{P}(Q \times \Gamma \times \{L, R\})$$

such that M accepts on an input as long as at least one branch of computation accepts.

Theorem 2.2.5. Let M be a NDTM and let $L = L(M)$. Then there exists a TM M' such that $L = L(M')$.

Proof. By Theorem 2.2.2, it suffices to construct a multi-tape TM that simulates M . Construct a tree with branches corresponding to threads of computation given by M and nodes corresponding to configurations of M . We construct a 3-tape TM D as follows.

Tape 1 always contains the input string w and nothing else. Tape 2 contains just the string on the tape of the current node. Setting $m = \max\{|A| : A \in \text{im } \delta\}$, tape 3 contains a string over $\{1, \dots, m\}$ that corresponds to the “address” of the current node.

We make D simulate a breadth-first search of the tree as follows.

1. Initialize tape 1 with w and tape 3 with ϵ .
2. Copy tape 1 to tape 2.
3. Move to the node given by the next symbol on tape 3.
4. Read the configuration of M on w that is determined by this node.
5. Accept or reject if this is an accepting or rejecting configuration, respectively.
6. Replace the current string on tape 3 with the next string under the string order.
7. Do step 1.

□

Note 2.2.6.

1. This simulation has time complexity $O(m^T)$ where T denotes the steps taken by M .
2. We can modify the proof of Theorem 2.2.5 to show that if M always halts on each branch of computation, then M' always halts. Thus, a language is decidable if and only if a NDTM decides it.

There is an injective function ι from the set of Turing machines into $\{0, 1\}^*$ because any TM's transition function admits a finite description. In particular, the set of TM is countable. Let $\langle M \rangle$ denote the binary encoding of the TM M . Let any $x \notin \text{im } \iota$ correspond to the TM that immediately halts and outputs zero on every input. As a result, every binary string corresponds to some Turing machine.

Theorem 2.2.7. *There is a TM (denoted by U_{TM}) taking two strings as inputs, $\langle M \rangle$ and x , (i.e., one string over $\{0, 1\} \times \Sigma$) such that*

- (a) *if M accepts x , then U_{TM} accepts,*
- (b) *if M rejects x , then U_{TM} rejects, and*
- (c) *if M does not halt on x , then neither does U_{TM} .*

Moreover, if M takes T steps on w , then U_{TM} takes $O(T \log T)$ steps on $\langle M, w \rangle$.

Proving Theorem 2.2.7 amounts to constructing an interpreter for a programming language within the language itself. See Theorem 1.13 (Arora and Barak) for a high-level proof.

Terminology. We call U_{TM} a *universal Turing machine*.

Aside. Let $f : \{0, 1\}^* \rightarrow \{0, 1\}^*$ be a partial computable function (see Definition 2.3.6 below). For any string σ , a *description of σ relative to f* is a string τ such that $f(\tau) = \sigma$. The *Kolmogorov complexity of σ relative to f* is

$$C_f(\sigma) \equiv \begin{cases} \min \{|\tau| \mid f(\tau) = \sigma\} & \sigma \in \text{im } f \\ \infty & \text{otherwise} \end{cases}.$$

To obtain an absolute definition of *Kolmogorov complexity*, let n_f denote the length of $\langle f \rangle$ and define a new partial computable function $g : \{0, 1\}^* \rightarrow \{0, 1\}^*$ by

$$0^{n_f} 1 \langle f \rangle y \mapsto U_{\text{TM}}(\langle f \rangle, y).$$

It is straightforward to prove that there is some constant $R \geq 0$ such that $C_g(\sigma) - C_f(\sigma) \leq R$ for every σ . Now, the *Kolmogorov complexity* of σ is $C(\sigma) \equiv C_g(\sigma)$.

We say that σ is *Kolmogorov random* if it cannot be compressed, formally, $C(\sigma) \geq |\sigma|$.

Proposition 2.2.8. *For every integer $n \geq 1$, there is a Kolmogorov random string of length n .*

Proof. Suppose not. Then for any string x of length n , $C(x) < n$. Hence there is some τ_x such that $g(\tau_x) = x$ and $|\tau_x| < n$. The mapping $x \mapsto \tau_x$ is clearly injective. But there are exactly 2^{n-1} strings of length $< n$ and exactly 2^n strings of length n . This yields a contradiction. \square

2.3 Lecture 7

Alternatively, we can view U_{TM} as a ternary function with input $\langle M, w, 1^k \rangle$ such that

- (i) *if M accepts (resp. rejects) on w in $\leq k$ steps, then U_{TM} accepts (resp. rejects) and*
- (ii) *if M does not halt on w in $\leq k$ steps, then U_{TM} will reach a special state.*

Lemma 2.3.1. *Let A_{TM} denote the language $\{\langle M, w \rangle \mid M \text{ accepts } w\}$. Then A_{TM} is recursively enumerable.*

Proof. Simply observe that $L(U_{\text{TM}}) = A_{\text{TM}}$. \square

Theorem 2.3.2. *A_{TM} is undecidable.*

Proof. Suppose, toward a contradiction, that there is some M that decides A_{TM} . Design a new TM N as follows.

- (a) Given a binary string x , run M on $\langle M_x, M_x \rangle$ where M_x denotes the TM corresponding to x .
- (b) Let N reject when M accepts and N accept when M rejects.

Then

$$N(\langle N \rangle) = \begin{cases} \text{accept} & N \text{ does not accept } \langle N \rangle \\ \text{reject} & N \text{ accepts } \langle N \rangle \end{cases},$$

which is impossible. □

Lemma 2.3.3. *If L is decidable, then \bar{L} is decidable.*

Lemma 2.3.4. *If both L and \bar{L} are recursively enumerable, then L is decidable.*

Proof. Find some M_1 and M_2 such that $L = L(M_1)$ and $\bar{L} = L(M_2)$. Construct some TM M as follows.

Algorithm 1: pseudocode describing M

Input: the string w

```

1   $T = 1$ ;
2  while the current state is a non-halting state do
3      run  $U_{\text{TM}}$  on  $\langle M_1, w \rangle$  for  $T$  steps;
4      if  $U_{\text{TM}}$  accepts then
5          | accept
6      else
7          run  $U_{\text{TM}}$  on  $\langle M_2, w \rangle$  for  $T$  steps ;
8          if  $U_{\text{TM}}$  accepts then
9              | reject
10         else
11             |  $T += 1$ 
12         end
13     end
14 end

```

□

Corollary 2.3.5. $\overline{A_{\text{TM}}}$ is not recursively enumerable.

Definition 2.3.6. A function $f : \Sigma^* \rightarrow \Sigma^*$ is *computable* if there is some TM M such that for any string w , M halts on w with its tape containing just $f(w)$.

Definition 2.3.7 (Reducibility). Let $L \subset \Sigma^*$ and $L' \subset \Sigma^*$ be languages. We say that L *many-one reduces* to L' , written as $L \leq_m L'$, if there is some computable function $f : \Sigma^* \rightarrow \Sigma^*$ such that

$$x \in L \iff f(x) \in L'.$$

In this case, we call f the *reduction* from L to L' .

Lemma 2.3.8. *Suppose that $L \leq_m L'$ and that L' is decidable (resp. recursively enumerable), then L is decidable (resp. recursively enumerable).*

Proof. Find some M that decides (resp. recognizes) L' and some reduction f from L to L' . Construct the TM N so that on input $w \in \Sigma^*$, we let N compute $f(w)$ and then output whatever M outputs on $f(w)$. Then N decides (resp. recognizes) L . \square

In this way, L' is at least as “hard” as L .

2.4 Lecture 8

Example 2.4.1 (Halting problem). Let $A_{\text{HALT}} = \{\langle M, w \rangle \mid M \text{ halts on } w\}$. Then A_{HALT} is undecidable.

Proof. Recall that A_{TM} is undecidable. Thus, it suffices to show that $A_{\text{TM}} \leq_m A_{\text{HALT}}$. To do this, we want to design a computable function that maps any $\langle M, w \rangle$ to another $\langle M', w' \rangle$ such that M' halts on w' precisely when M accepts w . Construct such an M' as follows.

Algorithm 2: pseudocode describing M'

Input: the string x

```

1 run  $U_{\text{TM}}$  on  $\langle M, x \rangle$ ;
2 if  $U_{\text{TM}}$  accepts then
3   | accept
4 else
5   | while true do
6     |   pass
7   | end
8 end
```

Then we get a suitable function given by $\langle M, w \rangle \mapsto \langle M', w' \rangle$. \square

Theorem 2.4.2 (Rice). *Let C be any subset of the universe of all languages over a fixed alphabet. Let*

$$L_C = \{\langle M \rangle : L(M) \in C\}.$$

Suppose that both L_C and $\overline{L_C}$ are nonempty. Then L_C is undecidable.

Proof. We may assume that $\emptyset \notin C$ for otherwise we could show that $\overline{L_C}$ is undecidable. We know that $L(M_y) \in C$ for some TM M_y . We show that $A_{\text{TM}} \leq_m L_C$. Consider any $\langle M, w \rangle \in A_{\text{TM}}$. Define M' as follows.

Algorithm 3: pseudocode describing M'

Input: the string x

```

1 run  $U_{\text{TM}}$  on  $\langle M, w \rangle$ ;
2 if  $U_{\text{TM}}$  accepts then
3   | run  $U_{\text{TM}}$  on  $\langle M_y, x \rangle$ 
4 else
5   | reject
6 end
```

If M accepts w , then $L(M') = L(M_y)$. If M rejects w , then $L(M') = \emptyset$. If M does not halt on w , then $L(M') = \emptyset$. \square

This means that every nontrivial semantic property of Turing machines is undecidable.

Example 2.4.3. Let $A_{\text{fin}} = \{\langle M \rangle : L(M) \text{ is finite}\}$. Then A_{fin} is undecidable.

In fact, we can strengthen Example 2.4.3.

Proposition 2.4.4. A_{fin} is not recursively enumerable.

Proof. Recall that $\overline{A_{\text{TM}}}$ is not recursively enumerable. We show that $\overline{A_{\text{TM}}} \leq_m A_{\text{fin}}$. Given any $\langle M, w \rangle$, define M' as follows.

Algorithm 4: pseudocode describing M'

Input: the string x

```

1 run  $U_{\text{TM}}$  on  $\langle M, w \rangle$ ;
2 if  $U_{\text{TM}}$  accepts then
3   | accept
4 else
5   | reject
6 end
```

If M accepts w , then $L(M') = \{0, 1\}^*$. Otherwise, $L(M') = \emptyset$. \square

Note 2.4.5. It's possible that both a language and its complement are not recursively enumerable.

3 Complexity theory

3.1 Lecture 9

Once we know that a problem is decidable, we want to determine the amount of computational resources required to decide it. Such resources include

time, space, parallelism, communication, rounds, and randomness.

We also want to study how these trade off with each other.

Definition 3.1.1 (Time complexity). Given any TM M , its *time complexity* is the function $f : \mathbb{N} \rightarrow \mathbb{N}$ where

$$f(n) \equiv \max\{\text{steps used by } M \text{ on input } w \mid |w| = n\}.$$

We say that M runs in time $f(n)$.

Let $f : \mathbb{N} \rightarrow \mathbb{N}$ be a *time-constructible* function, i.e., computable in $O(f(n))$ time with $f(n) \geq n$ for all $n \in \mathbb{N}$. Let

$$\text{DTIME}(f(n)) = \{L : \exists \text{ TM } M \text{ s.t. } L = L(M) \text{ and } M \text{ halts on all inputs of length } n \text{ in } O(f(n)) \text{ steps}\}$$

\Downarrow

$$\mathbf{P} = \bigcup_{k \geq 0} \text{DTIME}(n^k).$$

Note 3.1.2. Our definition of \mathbf{P} is independent of the variant of deterministic Turing machine used.

Remark 3.1.3. Given any convex body, we want to compute its volume. In 1989, Dyer and Frieze proved that this is solvable in $O(n^{23})$ steps. It is now known that it's solvable in $O(n^2)$ steps.

Example 3.1.4. For any $k \geq 0$, $\text{DTIME}(n^k) \subset \text{DTIME}(n^{k+1})$. Consider the case where $k = 2$. Then we can show that this containment is proper by using diagonalization. Indeed, define the language L as follows.

1. If x is of the form $w10^i$ for some w and some i , then let $x \notin L$.
2. Otherwise, let M_w be the TM corresponding to w .
3. In this case, run M_w on x for n^2 steps where n denotes $|x|$.
4. If M_w does not halt in so many steps, then let $x \notin L$.
5. Else, let $x \in L$ when M_w rejects and let $x \notin L$ when M_w accepts.

Steps 2 and 3 together take $O(n^2 \log n)$ steps. It follows that $L \in \text{DTIME}(n^2 \log n) \subset \text{DTIME}(n^3)$. But $L \notin \text{DTIME}(n^2)$.

Theorem 3.1.5 (Time hierarchy). *Let $f : \mathbb{N} \rightarrow \mathbb{N}$ be any function. Suppose that $g(n) = \omega(f(n) \log f(n))$. Then $\text{DTIME}(f(n)) \subsetneq \text{DTIME}(g(n))$.*

Definition 3.1.6. We say that a NDTM M has *time complexity* $t(n)$ if every branch of M runs in time $t(n)$.

Let

$$\begin{aligned} & \text{NTIME}(t(n)) \\ &= \{L : \exists \text{ NDTM } M \text{ s.t. } L(M) = L \text{ and every branch of } M \text{ halts on any input of length } n \text{ in } O(t(n)) \text{ steps}\} \\ \mathbf{NP} &= \bigcup_{k \geq 0} \text{NTIME}(n^k). \end{aligned}$$

Proposition 3.1.7. $\text{NTIME}(t(n)) \subset \text{DTIME}(2^{O(t(n))})$.

Example 3.1.8. Let φ be a Boolean formula in conjunctive normal form (CNF). Suppose that φ contains n clauses and m literals. Then the size of the representation in bits of φ is of order $O(2m \cdot n) = O(mn)$. Also, deciding whether φ evaluates to 1 takes $O(2m \cdot n) = O(mn)$ steps.

Let $\text{CNF-SAT} = \{\langle \varphi \rangle : \varphi \text{ is satisfiable}\}$. Notice that this can be decided by a nondeterministic Turing machine in linear time. There is, however, no known deterministic Turing machine running faster than brute force.

3.2 Lecture 10

Lemma 3.2.1. *A language L belongs to \mathbf{NP} if and only if there exist a deterministic TM $V(\cdot, \cdot)$ and constants $c_1, c_2 > 0$ such that*

$$L = \{x \mid \exists y (|y| \leq |x|^{c_1} \wedge V(x, y) = 1 \text{ where } V \text{ runs in time } |x \cdot y|^{c_2})\}.$$

Terminology. In this case, we call V a *verifier* and y a *witness*.

Proof.

(\implies)

There is some NDTM M running in polynomial time such that $L(M) = L$. Say that M runs in time n^c . The sequence of choices along any branch of M can be represented by a binary string of length n^c . Define V as the algorithm taking inputs x and y with $y \in \{0, 1\}^{n^c}$ and executing M on x with choice of branch given by y . Then V runs in polynomial time, and $x \in L \iff V(x, y) = 1$ for some y .

(\impliedby)

Given an input x , define a NDTM M that first guesses a witness y in a separate tape and then runs V on (x, y) in polynomial time. \square

Note 3.2.2. Equivalently, we could have made V run in time $|x|^{c^2}$ while dropping the requirement that $|y|$ be polynomial in $|x|$.

Definition 3.2.3. An *independent set* of a graph $G = (V, E)$ is a set $I \subset V$ such that no two points in I are connected by an edge.

Example 3.2.4. The following languages are in **NP**.

1. IND-SET := $\{\langle G, k \rangle : G \text{ is an (undirected) graph with an independent set of size at least } k\}$
2. 3-COLOR := $\{\langle G \rangle : G \text{ has a 3-coloring}\}$.
3. Composite := $\{x \mid x \text{ is a composite number}\}$.
4. PRIMES := $\{n \mid n \text{ is prime}\}$.

Definition 3.2.5. We say that L_1 *polynomially many-one reduces to* L_2 (written as $L_1 \leq_m^p L_2$) if there is some TM M running in polynomial time such that $x \in L_1 \iff M(x) \in L_2$.

Lemma 3.2.6. *If $L_1 \leq_m^p L_2$ and $L_2 \in \mathbf{P}$, then $L_1 \in \mathbf{P}$.*

Definition 3.2.7. We say that L is **NP**-complete if $L \in \mathbf{NP}$ and for any $L' \in \mathbf{NP}$, $L' \leq_m^p L$.

3.3 Lecture 11

Definition 3.3.1. A (*Boolean*) *circuit* is a directed acyclic graph with a unique sink node such that

- (i) each node has indegree at most 2,
- (ii) each internal node is labelled by \wedge , \vee , or \neg ,
- (iii) each leaf node is labeled by a Boolean variable, and
- (iv) each edge is labeled by the Boolean value given by the output of the prior node.

The *size* of a circuit is the number of its internal nodes.

Remark 3.3.2. This is an example of a non-uniform model of computation as we must specify a new circuit for each input size.

Lemma 3.3.3. *Every function $g : \{0, 1\}^n \rightarrow \{0, 1\}$ can be computed by a circuit of size $O(2^n)$.*

Proof. We use induction to show that any function $g : \{0, 1\}^n \rightarrow \{0, 1\}$ can be computed by a circuit of size at most $3 \cdot 2^n - 4$, which is enough. When $n = 1$, there are four cases to consider.

- (a) If $g = \text{id}_{\{0,1\}}$, then g can be computed by a circuit of size 0.
- (b) If $g(0) = 1$ and $g(1) = 0$, then $g(x) = \neg x$.
- (c) If $g(0) = g(1) = 0$, then $g(x) = x \wedge \neg x$.
- (d) If $g(0) = g(1) = 1$, then $g(x) = x \vee \neg x$.

Hence the base case holds. Now, define $g_0, g_1 : \{0, 1\}^{n-1} \rightarrow \{0, 1\}$ by $g_0(y) = g(0, y)$ and $g_1(y) = g(1, y)$. Then g satisfies

$$g(y) = (\neg y_1 \wedge g_0(y_2, \dots, y_n)) \vee (y_1 \wedge g_1(y_2, \dots, y_n))$$

for each y . By induction, g can be computed by a circuit of size at most $4 + 2(3 \cdot 2^{n-1} - 4) = 3 \cdot 2^n - 4$. \square

Lemma 3.3.4. *Let $M = (Q, \Sigma, \Gamma, q_0, \delta, Q_F, Q_R)$ be a TM. Suppose that on any input of size n , M halts in at most t steps with $t \geq n$. Then there is a circuit of size $O(t^2 \cdot (|\Gamma| \cdot |Q|)^3) = O(t^2)$ that outputs 1 on a string x of length n if and only if M accepts x .*

Proof. We want to encode a given configuration of M , which we may assume uses at most t cells of tape. To do this, we take $\log |\Gamma|$ bits, 1 bit, and $\log |Q|$ bits to encode the content of the current cell, whether or not the head is located at this cell, and, if so, the current state, respectively. For each $i, j \geq 0$, the bit $b_{j,l+1}$ representing the j -th cell at time $l + 1$ depends precisely on the three bits $b_{j-1,l}$, $b_{j,l}$, and $b_{j+1,l}$. Let $B = 1 + \log |\Gamma| + \log |Q|$. Then every bit of the encoding of the configuration of M at time $l + 1$ depends on $3B$ bits. This determines a Boolean function $f : \{0, 1\}^{3B} \rightarrow \{0, 1\}$ that computes the next configuration. Lemma 3.3.3 implies that f can be computed by a circuit of size $O(2^{3B})$ and hence by one of size $O((|\Gamma| \cdot |Q|)^3)$. Thus, there is a circuit of size $O(t \cdot t \cdot (|\Gamma| \cdot |Q|)^3)$ that simulates M on inputs of size n . \square

Example 3.3.5 (Cook-Levin theorem). Let $\text{CIRCUIT-SAT} = \{\langle C \rangle : \exists x (C(x) = 1)\}$. This is certainly in **NP**. We claim that it is **NP**-complete.

Proof. If $L \in \mathbf{NP}$, then there is an efficient (i.e., polynomial time) algorithm V such that

$$(\forall x \in L) (\exists y \in \Sigma^*) \left(|y| \leq |x|^{O(1)} \wedge V(x, y) = 1 \wedge (x \notin L \implies \forall y (V(x, y) = 0)) \right).$$

Thus, for each $n \in \mathbb{N}$, we can use Lemma 3.3.4 to construct a circuit of size $n^{O(1)}$ such that $C(x, y) = V(x, y)$ for each string x of size n and each string y with $|y| \leq n^{O(1)}$. This means that for each string x , we can construct a circuit $C_x(\cdot)$ of size $|x|^{O(1)}$ such that $C_x(y) = V(x, y)$ for any y with $|y| \leq |x|^{O(1)}$. The mapping $M : x \mapsto \langle C_x(\cdot) \rangle$ satisfies $x \in L \iff M(x) \in \text{CIRCUIT-SAT}$, as desired. \square

3.4 Lecture 12

Corollary 3.4.1. *Showing that CIRCUIT-SAT is not in \mathbf{P} is equivalent to showing that $\mathbf{P} \neq \mathbf{NP}$.*

Corollary 3.4.2. *Suppose that CIRCUIT-SAT $\leq_m^p L$ and $L \in \mathbf{NP}$. Then any $L' \in \mathbf{NP}$ satisfies $L' \leq_m^p L$, i.e., L is \mathbf{NP} -complete.*

Both Corollary 3.4.1 and Corollary 3.4.2 hold with CIRCUIT-SAT replaced by any \mathbf{NP} -complete language.

Definition 3.4.3. A Boolean formula in CNF is a *3cnf formula* if each clause contains exactly 3 literals.

Example 3.4.4.

1. Consider $3\text{-SAT} := \{\langle \varphi \rangle \mid \varphi \text{ is a 3cnf formula that is satisfiable}\}$. This is certainly in \mathbf{NP} . We claim that it is \mathbf{NP} -complete.

Proof. It suffices to show that $\text{CIRCUIT-SAT} \leq_m^p 3\text{-SAT}$. We must construct an efficient algorithm $M(-)$ such that the circuit C is satisfiable if and only if $\varphi := M(\langle C \rangle)$ is satisfiable. If C has size n , then, wlog, we can use the associativity of our Boolean operations to add at most n^k internal nodes to C such that each gate labeled by \wedge or \vee takes exactly two inputs.

Let g_1, \dots, g_n and x_1, \dots, x_m denote the Boolean values given by the edges and inputs of C , respectively. Relabel $g_1, \dots, g_n, x_1, \dots, x_m$ as w_1, \dots, w_{n+m} . Let φ be the 3cnf formula in the variables w_1, \dots, w_{n+m} where each clause of φ corresponds either to C 's output value $w_s \vee w_s \vee w_s$ or to one of C 's internal edges. In the latter case, we can give the following descriptions.

- If $w_j = \neg w_i$, then φ contains exactly one clause of the form

$$(w_i \vee w_j) \wedge (\neg w_i \vee \neg w_j).$$

- If $w_h = w_i \wedge w_j$ in C , then φ contains exactly one clause of the form

$$(w_i \vee w_j \vee \neg w_h) \wedge (w_i \vee \neg w_j \vee \neg w_h) \wedge (\neg w_i \vee w_j \vee \neg w_h) \wedge (\neg w_i \vee \neg w_j \vee w_h).$$

- If $w_h = w_i \vee w_j$ in C , then φ contains exactly one clause of the form

$$(w_i \vee w_j \vee \neg w_h) \wedge (w_i \vee \neg w_j \vee w_h) \wedge (\neg w_i \vee w_j \vee w_h) \wedge (\neg w_i \vee \neg w_j \vee w_h).$$

By construction, φ is satisfiable if and only if C is. The algorithm $M : \langle C \rangle \mapsto \varphi$ is linear in n^k , hence efficient. Therefore, it is a suitable reduction. \square

2. It's clear that IND-SET belongs to NP. We claim that this is NP-complete.

Proof. We show that 3-SAT \leq_m^p IND-SET. Let φ be a 3cnf-formula and let

$$\varphi = c_1 \wedge c_2 \wedge c_3 \wedge \cdots \wedge c_m.$$

For each clause c_i , create a triangle t_i with vertices corresponding to the three literals in c_i . Let G_φ denote the graph obtained from the graph $\coprod_{i=1}^m t_i$ by adding an edge between any two conflicting vertices v and $\neg v$ in $\coprod_{i=1}^m t_i$. Then the algorithm $\varphi \mapsto \langle G_\varphi, m \rangle$ defines a suitable reduction. \square

3. We say that $K \subset V$ is a *vertex cover* of a graph $G = (V, E)$ if any edge $(x, y) \in E$ has $x \in K$ or $y \in K$. Let $\text{VC} = \{\langle G, k \rangle \mid G \text{ has a vertex cover of size at most } k\}$. Then IND-SET \leq_m^p VC, so that VC is NP-complete.

Proof. Let G be a graph with an independent set S with $|S| \geq k$. Then $V \setminus S$ is a vertex cover of G . Conversely, if G has a vertex cover K of size at most $|V| - k$, then $V \setminus K$ is an independent set of size at least k in G . Thus, the algorithm $\langle G, k \rangle \mapsto \langle G, |V| - k \rangle$ defines a suitable reduction. \square

3.5 Lecture 13

Definition 3.5.1. We say that a language L is *NP-hard* if $L' \leq_m^p L$ for any $L' \in \text{NP}$.

Definition 3.5.2. Let $G = (V, E)$ be a graph

1. A subset $C \subset V$ is a *clique* in G if any two distinct points in C are adjacent. Let

$$\text{CLIQUE} = \{\langle G, k \rangle \mid G \text{ has a clique of size at least } k\}.$$

2. The graph $\overline{G} = (V, E')$ where $E' \equiv \{(x, y) \mid (x, y) \notin E\}$ is the *complement graph* of G .

Proposition 3.5.3. A set S of vertices in a graph G is an independent set in G if and only if it is a clique in \overline{G} .

Example 3.5.4. IND-SET \leq_m^p CLIQUE via the mapping $\langle G, k \rangle \mapsto \langle \overline{G}, k \rangle$. Hence CLIQUE is NP-hard.

Definition 3.5.5. Let $G = (V, E)$ be an (undirected) weighted graph with weight function $w : E \rightarrow \mathbb{R}_{\geq 0}$. Suppose that $C \subset V$. A *Steiner tree* in G is a connected subgraph of G with no cycles that contains each vertex in C .

Remark 3.5.6. Any connected subgraph of minimum weight must be a tree.

Problem. Given a weighted graph G and set of vertices C in G , find the Steiner tree in G of minimum weight that contains C .

Definition 3.5.7. Let $G = (V, E)$. A subset $C \subset V$ has a *Steiner tree of total weight W* if there exists a connected subgraph of G that contains every vertex in C and has weight at most W .

Example 3.5.8. Let $\text{Steiner-tree} = \{\langle G, C, W \rangle \mid C \text{ has a Steiner tree of total weight at most } W\}$. This is NP-complete.

Proof. It's clear that Steiner-tree belongs to **NP**. To show that it is also **NP**-hard, we prove that $\text{VC} \leq_m^p \text{Steiner-tree}$. Let $G = (V, E)$ be a graph with a vertex cover S of size k . Let

$$V' = \bigcup_{v \in V} [v] \bigcup_{(u,v) \in E} [u, v].$$

Build E' as follows.

- (a) Let $([u], [v]) \in E'$ for any $u, v \in V$ and set $w'([u], [v]) = 1$.
- (b) If $(u, v) \in E$, then let $([u], [u, v]), ([u, v], [v]) \in E'$ and set $w'([u], [u, v]) = w'([u, v], [v]) = 1$.
- (c) If $(v, w) \in E$ and u, v, w are pairwise distinct, then let $([u], [v, w]) \in E'$ and set $w'([u], [v, w]) = 2$.
- (d) Finally, for any $(u, v), (w, z) \in E$, let $([u, v], [w, z]) \in E'$ with weight

$$w'([u, v], [w, z]) \equiv \begin{cases} 2 & (u, v) \text{ and } (w, z) \text{ share a vertex} \\ 3 & \text{otherwise} \end{cases}.$$

Set $C = \{[u, v] : (u, v) \in E\}$. Also, set $W = |E| + k - 1$. Let $G' = (V', E', w')$. Note that we have constructed G' in polynomial time.

Claim. G' has a Steiner tree containing C with weight at most $|E| + k - 1$.

Proof. Let $S = \{v_1, \dots, v_k\}$. Let

$$S' = \left\{ [v_1], \dots, [v_k], \bigcup_{(u,v) \in E} [u, v] \right\}$$

$$E_{S'} = \{(x, y) \in E' \mid w'(x, y) = 1 \text{ and } x, y \in S'\}.$$

Since S is a vertex cover, we see that $(S', E_{S'})$ is a connected subgraph of G' that contains C and has weight $|E| + k - 1$. \square

Claim. If C has a Steiner tree T of total weight $W \leq |E| + k - 1$, then G has a vertex cover of size k .

Proof. Alter T as follows.

- Replace any edge of weight 2 between $[w]$ and $[u, v]$ with the edges $([w], [u])$ and $([u], [u, v])$.
- Replace any edge of weight 2 between $[u, v]$ and $[v, w]$ with the edges $([u, v], [v])$ and $([v], [v, w])$.
- Replace any edge of weight 3 between $[u, v]$ and $[w, z]$ with the edges $([u, v], [v]), ([v], [w]),$ and $([w], [w, z])$.

The resultant graph T' is connected and contains C . Note that T' has weight at most $|E| + k - 1$ where each edge of T' has weight 1. This implies that T' spans at most $|E| + k$ vertices. Since T' contains C , it follows that T' contains a set R of vertices of the form $[v]$ such that $|R| \leq k$. If $(x, y) \in E$, then $[x, y]$ is connected to some $[v_0]$ by edges of weight 1. This means that $[x]$ or $[y]$ belongs to T' , so that $[x]$ or $[y]$ belongs to R . This shows that R is a vertex cover for G . \square

□

Remark 3.5.9. Any undirected weighted (connected) graph can be endowed with a metric by taking the shortest path between any two vertices. Our choice of weights in part (d) of our construction of E' makes G' a metric space.

Example 3.5.10. The language

$$\text{SUBSET-SUM} := \left\{ \langle a_1, \dots, a_k, t \rangle \mid a_i, t \geq 0, \exists S \subset [k]. \sum_{i \in S} a_i = t \right\}.$$

is **NP**-complete.

Proof. It's clear that this belongs to **NP**. We show that $\text{VC} \leq_m^p \text{SUBSET-SUM}$. Let $G = (V, E)$ such that $|V| = n$ and $|E| = m$. We can make E totally ordered. Suppose that G has a vertex cover C of size k . For each $v \in V$, we define an integer $a_v \geq 0$ in base-4 (written from left to right) consisting of $m + 1$ digits. Further, for each $e \in E$, we define an integer $b_e \geq 0$ in base-4 consisting of $m + 1$ digits. Specifically, if $0 \leq i \leq |E| - 1$ and $(u, v) \in E$ is the i -th edge, then define both a_u and a_v as the integer

$$0 \dots 0 \underset{\substack{i\text{-th} \\ \text{digit}}}{1} 0 \dots 01$$

and define $b_{(u,v)}$ as the integer

$$0 \dots 0 \underset{\substack{i\text{-th} \\ \text{digit}}}{1} 0 \dots 00.$$

Now, set $t = k \cdot 4^m + \sum_{i=0}^{m-1} 2 \cdot 4^i$.

Let $S = \{a_v \mid v \in C\} \cup \{b_{(u,v)} \mid \text{exactly one of } u \text{ and } v \text{ belongs to } C\}$. Note that we can construct S in polynomial time. It's straightforward to check that the terms of S sum to t .

Claim. Suppose that there are subsets $U \subset V$ and $T \subset E$ such that

$$t = \sum_{u \in U} a_u + \sum_{(u,v) \in T} b_{(u,v)}.$$

Then U is a vertex cover for G of size at most k .

Proof. Since $t < (k + 1)4^m$ and each $a_u > 4^m$, it follows that $|U| \leq k$. Note that, in base-4, each of the first m digits of t equals 2. Thus, for each $(u, v) \in E$, at least two of a_u , a_v , and $b_{(u,v)}$ contribute to the summation

$$\sum_{u \in U} a_u + \sum_{(u,v) \in T} b_{(u,v)}.$$

This implies that at least one of u and v belongs to U . Hence U is a vertex cover for G . □

□

Remark 3.5.11. By using dynamic programming, one can show that there is a $\text{poly}(k, t)$ algorithm deciding SUBSET-SUM. This result, however, does not imply that SUBSET-SUM $\in \mathbf{P}$, because the size of the whole input $\langle a_1, \dots, a_k, t \rangle$ is on the order of $k \log t$.

3.6 Lecture 14

Let $S : \mathbb{N} \rightarrow \mathbb{N}$. Unless we state otherwise, we assume that $S(n) \geq \log n$. Consider the *space complexity class* $\text{DSPACE}(S(n))$ consisting of all languages L for which

\exists TM M s.t. $L = L(M)$ and on any input of length n , M touches at most $S(n)$ cells (on its work tape).

Further, let $\text{NSPACE}(S(n))$ consist of all languages L for which there is some NDTM M s.t. $L = L(M)$ and on any input of length n , M halts on every branch of computation and touches at most $S(n)$ cells on any branch.

Definition 3.6.1. Let M be a Turing machine that always halts. Define the *configuration graph* $G_{M,x}$ of M on input x as the directed graph (V, E) where V consists of the possible configurations of M on x and $E \equiv \{(C, C') : C \vdash C'\}$.

By making M erase the contents of its work tapes right before halting, we may assume that M has exactly one accepting configuration C_{accept} on x . Moreover, since M always halts, it can never reach the same configuration more than once. Thus, $G_{M,x}$ is a directed acyclic graph.

Lemma 3.6.2. $\text{NSPACE}(S(n)) \subset \text{DTIME}(2^{O(S(n))})$.

Proof. Let $L \in \text{NSPACE}(S(n))$ with $L(M) = L$. Given any input x of length n , we can use $O(S(n))$ bits to describe the current contents of the tape, $O(\log S(n))$ bits to describe the current state, and $O(1)$ bits to describe the current location of the head. Thus, we need

$$O(S(n)) + O(1) + O(\log S(n)) = O(S(n))$$

bits to describe any vertex of $G_{M,x}$.

Note that the number of configurations of M is at most $2^{O(S(n))}$ (provided that any configuration of a NDTM yields at most two distinct configurations). Therefore, we can construct $G_{M,x}$ in $2^{O(S(n))}$ steps. Now apply the standard linear time breadth-first search for connectivity to $G_{M,x}$ to decide if there is a path from C_{start} to C_{accept} . \square

Corollary 3.6.3.

1. $\text{DTIME}(S(n)) \subset \text{DSPACE}(S(n)) \subset \text{NSPACE}(S(n)) \subset \text{DTIME}(2^{O(S(n))})$.
2. $\text{DTIME}(S(n)) \subset \text{NTIME}(S(n)) \subset \text{NSPACE}(S(n))$.

Remark 3.6.4. It is not known whether these chains of containment can be improved.

Notation.

1. $\text{PSPACE} := \bigcup_{k \geq 0} \text{DSPACE}(n^k)$.
2. $\text{NPSPACE} := \bigcup_{k \geq 0} \text{NSPACE}(n^k)$.

Note 3.6.5.

1. $\mathbf{P} \subset \text{PSPACE}$.
2. $\mathbf{NP} \subset \text{NPSPACE}$.

Proposition 3.6.6. *Let $\mathbf{L} = \text{DSPACE}(\log n)$ and $\mathbf{NL} = \text{NSPACE}(\log n)$.*

1. *Let $L_1 = \{\langle x, y, z \rangle \mid x \cdot y = z\}$ and $L_2 = \{\langle x, y, z \rangle \mid x + y = z\}$. Then $L_1, L_2 \in \mathbf{L}$.*
2. *Let $\text{DIR-REACH} = \{\langle G, s, t \rangle \mid G \text{ is directed and the vertex } t \text{ is reachable from } s\}$. Then $\text{DIR-REACH} \in \mathbf{NL}$.*

Remark 3.6.7. Omer Reingold has shown that

$$\text{REACH} := \{\langle G, s, t \rangle \mid G \text{ is undirected and the vertex } t \text{ is reachable from } s\}$$

belongs to \mathbf{L} .

Recall that $\text{NTIME}(S(n)) \subset \text{DTIME}(2^{O(S(n))})$. The corresponding relation for space complexity, however, is much better.

Theorem 3.6.8 (Savitch). $\text{NSPACE}(S(n)) \subset \text{DSPACE}(S^2(n))$.

Corollary 3.6.9. $\text{PSPACE} = \text{NPSPACE}$.

3.7 Lecture 15

Proof of Theorem 3.6.8. Let $L \in \text{NSPACE}(S(n))$ with $L(M) = L$. Recall that the configuration graph $G_{M,x}$ has at most $T_0 := 2^{O(S(n))}$ nodes. Consider the following recursive algorithm.

Input: the string x

```

1 for  $j \in \{1, \dots, T_0\}$  do
2   if  $\text{REACH}(C_{\text{start}}, j, \frac{T_0}{2})$  and  $\text{REACH}(j, C_{\text{accept}}, \frac{T_0}{2})$  then
3     output "yes"
4   else
5     output "no"
6   end
7 end
```

Denote the space complexity of the preceding algorithm by $\mathcal{L}(T_0)$. Note that we can reuse the space used by the first recursive call for the second recursive call. Since we need $\log T_0$ cells to encode the counter, it follows that

$$\mathcal{L}(T_0) = \log T_0 + \mathcal{L}(T_0/2) + O(1).$$

Note that the recursion depth here is precisely $\log T_0$. Using this, we compute

$$\begin{aligned} \mathcal{L}(T_0) &= \log T_0 + \mathcal{L}(T_0/2) \\ &= \log^2 T_0 + \mathcal{L}(1) \\ &= \log^2 2^{O(S(n))} + \mathcal{L}(1) \\ &= O(S^2(n)) + O(S(n)) \\ &= O(S^2(n)). \end{aligned}$$

□

Corollary 3.7.1. $\text{NL} \subset \text{P}$.

Proof. This follows because DIR-REACH is **NL**-complete and, by our proof of Theorem 3.6.8, has a $\log^2 n$ -space deterministic algorithm. \square

Note 3.7.2.

1. $\text{NTIME}(\text{poly}(n)) \subset \text{NPSACE}(\text{poly}(n)) \subset \text{DPSACE}(\text{poly}(n)) = \text{PSPACE}$.
2. PSPACE is closed under complementation.

Example 3.7.3.

1. Let $\Sigma_2\text{-SAT} = \{\varphi \text{ Boolean} \mid \forall \bar{x} \exists \bar{y} (\varphi(\bar{x}, \bar{y}) = 1)\}$. It is unclear that this (or its complement) belongs to **NP**.
2. Consider the language

$$\text{TQBF-SAT} = \{\varphi(\bar{x}_1, \dots, \bar{x}_n) \mid Q_1 \bar{x}_1 Q_2 \bar{x}_2 Q_3 \bar{x}_3 \cdots Q_n \bar{x}_n (\varphi(\bar{x}_1, \dots, \bar{x}_n) = 1), Q_i \in \{\forall, \exists\}\}$$

of all *totally quantified Boolean formulas*. This belongs to PSPACE.

Proof. Construct an algorithm $T(\varphi)$ as follows.

- If φ is quantifier-free, then evaluate it directly.
Accept if it evaluates to 1 and reject otherwise.
- If $\varphi = \exists x \psi$, then recursively call T on ψ once with $x = 0$ and once with $x = 1$.
Accept if either of these recursive calls accepts and reject otherwise.
- If $\varphi = \forall x \psi$, then recursively call T on ψ once with $x = 0$ and once with $x = 1$.
Accept if both of these recursive calls accept and reject otherwise.

If m denotes the size of φ , then

$$\mathcal{L}(m) = m^{O(1)} + \mathcal{L}(m-1) + O(1) = m^{O(1)} + \mathcal{L}(m-1) = O(m^k)$$

for some k . \square

3.8 Lecture 16

Definition 3.8.1. A language L is *PSPACE-complete* if it belongs to PSPACE and for any $L' \in \text{PSPACE}$, $L' \leq_m^p L$.

Example 3.8.2. TQBF-SAT is PSPACE-complete.

Proof. Let $L \in \text{PSPACE}$ with $L(M) = L$. Given any input x with $|x| = n$, we want to construct a TQBF $\varphi_{c,c',i}$ of size $O(S(n)^2)$ that is satisfiable if and only if there is a path of length at most 2^i from c to c' in the configuration graph $G_{M,x}$. This will imply that

$$\hat{\varphi} := \varphi_{C_{\text{start}}, C_{\text{accept}}, O(S(n))}$$

is true if and only if M accepts x , i.e., $x \in L$.

We have previously constructed such a $\varphi_{c_1, c_2, 0}$. Moreover, if $i \geq 1$, then we deduce that

$$\begin{aligned} \varphi_{c_1, c_2, i} &\leftrightarrow \exists c (\varphi_{c_1, c, i-1} \wedge \varphi_{c, c_2, i-1}) \\ &\leftrightarrow \exists c \forall D^1 \forall D^2 ((D^1 = c_1 \wedge D^2 = c) \vee (D^1 = c) \wedge (D^2 = c_2)) \implies \varphi_{D^1, D^2, i-1}. \end{aligned}$$

It follows that $|\varphi_{c_1, c_2, i}| \leq |\varphi_{c_1, c_2, i-1}| + O(S(n))$, so that $|\hat{\varphi}| \leq O(S(n)^2)$, as desired. \square

Proposition 3.8.3. *A language L belongs to \mathbf{NL} if and only if there exists $c \in \mathbb{N}$ along with a deterministic TM $V(\cdot, \cdot)$ consisting of*

- one read-only input tape,
- one work tape, and
- one read-only, single-axis proof tape such that
- V 's work tape uses $O(\log |(\text{first input})|)$ space and

$$L = \{x \mid \exists y (|y| \leq |x|^c \wedge V(x, y) = 1)\}.$$

3.9 Lecture 17

Definition 3.9.1.

1. Let M be a TM consisting of one read-only input tape, one work tape, and one write-only, single-axis output tape such that M 's work tape uses $O(\log n)$ space. We call such an M a *log space transducer*.
2. Let A and B be languages. We say that A is *log space reducible to B* , written as $A \leq_l B$, if there is some log space transducer $M : \Sigma^* \rightarrow \Sigma^*$ such that $x \in A \iff M(x) \in B$.
3. A language L is *\mathbf{NL} -complete* if it belongs to \mathbf{NL} and $L' \leq_l L$ for any $L' \in \mathbf{NL}$.

Proposition 3.9.2. *If $L \in \mathbf{NL}$ and $L' \leq_l L$, then $L' \in \mathbf{NL}$.*

Example 3.9.3. DIR–REACH is \mathbf{NL} -complete.¹

Theorem 3.9.4 (Immerman-Szelepcsényi).

$$\mathbf{NL} = \mathbf{co-NL}.$$

(In general, $\mathbf{co-C}$ denotes the set of all languages whose complements belong to the complexity class \mathbf{C} .)

Proof. Since DIR–REACH is \mathbf{NL} -complete, it suffices to show that $\text{DIR–REACH}^c \in \mathbf{NL}$. Let $G = (V, E)$ be a graph of size n and $s, t \in V$. Let C_i denote the set of vertices $v \in V$ reachable from s in at most i steps. We can assume that V is ordered as (v_1, \dots, v_n) since each index can be described in $\log n$ bits.

First, let $v \in V$. Given that $|C_i| = k$, we can verify that $v \notin C_i$ as follows.

1. Propose a list v_{s_1}, \dots, v_{s_m} of vertices and a path $s \rightsquigarrow v_{s_i}$ for each $1 \leq i \leq m$.

¹Theorem 4.16 (Arora and Barak).

2. Write the next v_{s_i} on the work tape and write the proposed path $s \rightsquigarrow v_{s_i}$ on the proof tape.
3. Verify that the proposed path is valid. If not, then *reject*.
4. Otherwise, verify that $s_i > s_{i-1}$ and $v_{s_i} \neq v$. If not, then *reject*.
5. Repeat steps 2-4 until there is no v_{s_i} left.
6. Verify that $m = k$ by using a counter on the work tape. If not, then *reject*. Otherwise, *accept*.

Second, given that $|C_{i-1}| = k$, we can verify that $v \notin C_i$ as follows.

1. Propose a list v_{s_1}, \dots, v_{s_m} of vertices and a path $s \rightsquigarrow v_{s_i}$ for each $1 \leq i \leq m$.
2. Write the next v_{s_i} on the work tape and write the proposed path $s \rightsquigarrow v_{s_i}$ on the proof tape.
3. Verify that the proposed path is valid. If not, then *reject*.
4. Otherwise, verify that $s_i > s_{i-1}$, $v_{s_i} \neq v$, and v_{s_i} is not a neighbor of v . If not, then *reject*.
5. Repeat steps 2-4 until there is no v_{s_i} left.
6. Verify that $m = k$ by using a counter on the work tape. If not, then *reject*. Otherwise, *accept*.

Finally, let $c \in \mathbb{N}$. Given that $|C_{i-1}| = k$, we can verify that $|C_i| = c$ as follows.

1. Write the next v_i on the work tape (where $1 \leq i \leq n$).
2. Decide if $v_i \in C_i$ using our two preceding algorithms.
3. Repeat steps 1-2 until there is no v_i left.
4. Determine the number r of vertices in C_i by using a counter on the work tape. If $r = c$, then *accept*. Otherwise, *reject*.

Note that each of our three verifiers uses $O(\log n)$ space on its work tape and is polynomial in n on its proof tape. Apply our final algorithm iteratively n times to verify the size of C_n . Since we can reuse space on the work tape, our space complexity on it remains $O(\log n)$. Next, run our first algorithm to verify that $t \notin C_n$, in which case t is not reachable from s . \square

Corollary 3.9.5. *If $s(n) \geq \log n$, then $\text{NSPACE}(s(n)) = \text{co-NSPACE}(s(n))$.*

Remark 3.9.6. Thanks to Bertrand's postulate, some prime number between N and $2N$ always exists. Suppose that we want to find the least such prime \tilde{p} . Consider the probability \mathbb{P} that a randomly chosen number between N and $2N$ is prime. From the prime number theorem, it is known that $\mathbb{P} \approx \frac{N}{\log N}$. As a result, we can run the AKS primality test $O(\log N)$ times to find \tilde{p} with high probability.

3.10 Lecture 18

Definition 3.10.1 (Probabilistic Turing machine).

1. We call a TM a *probabilistic/randomized Turing machine* if it consists of an input tape, a work tape, and a “random bits” tape.
2. Let $p : \mathbb{N} \rightarrow \mathbb{N}$ be a polynomial. A probabilistic TM $M(\cdot, \cdot)$ *decides* L with respect to p if
 - for any $x \in L$, $\mathbb{P}_{r \in_R \{0,1\}^{p(|x|)}} [M(x, r) = 1] \geq \frac{2}{3}$ and
 - for any $x \notin L$, $\mathbb{P}_{r \in_R \{0,1\}^{p(|x|)}} [M(x, r) = 0] \geq \frac{2}{3}$.

Definition 3.10.2. A language L belongs to

$$\underbrace{\text{BPTIME}(t(n))}_{\text{bounded error probabilistic time}}$$

if there exists a randomized TM M running in time $t(|x|)$ (with probability 1) such that M decides L with respect to $t(n)$. Let $\mathbf{BPP} = \bigcup_{c \geq 0} \text{BPTIME}(n^c)$.

Note 3.10.3. It's clear that $\mathbf{P} \subset \mathbf{BPP}$.

Proposition 3.10.4. $\mathbf{P} \neq \mathbf{NP} \implies \mathbf{P} = \mathbf{BPP}$.

Remark 3.10.5.

1. Computing the value of the determinant of an $n \times n$ matrix of integers via cofactor expansion takes $\omega(n!)$ steps. Computing it via Gaussian elimination, however, takes $O(n^3)$ steps.
2. Computing the value of the determinant of an $n \times n$ matrix of linear forms over \mathbb{Z} via cofactor expansion is exponential in n . There is no known deterministic polynomial time algorithm for such a computation.

Proposition 3.10.6.

- (a) Let L be an $n \times n$ matrix of linear forms in $\mathbb{Z}[x_1, \dots, x_n]$ whose coefficients are in $[-2^n, 2^n]$. Then $\det L$ is a polynomial in x_1, \dots, x_n with (total) degree n and each coefficient an integer $\leq 2^{O(n^2)}$.
- (b) Let $p(x)$ be a univariate polynomial of degree $d \geq 0$. Let $S \subset \mathbb{Z}$ be finite. Then

$$\mathbb{P}[p(x) = 0] \leq \frac{d}{|S|}$$

for any $x \in_R S$.

Lemma 3.10.7 (DeMillo-Lipton-Schwartz-Zippel). Let $p(x_1, \dots, x_n)$ be a multivariate polynomial of degree at most $d \geq 0$. Let $S \subset \mathbb{Z}$ be finite. Then for any elements a_1, \dots, a_n randomly chosen with replacement from S ,

$$\mathbb{P}[p(a_1, \dots, a_n) = 0] \leq \frac{d}{|S|}.$$

Proof. We use induction on n . If $n = 1$, then this is exactly Proposition 3.10.6(b). Now, we can write

$$p(x_1, \dots, x_n) = \sum_{i=0}^d = x_1^i q_i(x_2, \dots, x_n)$$

where $\deg q_i \leq d - i$ for each i . Let k be maximal such that $q_k(x_2, \dots, x_n) \neq 0$. Let E denote the event that $q_k(x_2, \dots, x_n) = 0$. By induction together with Proposition 3.10.6(b), it follows that

$$\begin{aligned} \mathbb{P}[p(a_1, \dots, a_n) = 0] &\leq \mathbb{P}[E] + \mathbb{P}[p(a_1, \dots, a_n) = 0 \mid \neg E] \\ &\leq \frac{d-k}{|S|} + \frac{k}{|S|} = \frac{d}{|S|}. \end{aligned}$$

□

Example 3.10.8. Let L be an $n \times n$ matrix of linear forms in $\mathbb{Z}[x_1, \dots, x_n]$ whose coefficients are in $[-2^n, 2^n]$. Define the probabilistic TM A on input $\langle L \rangle$ as follows.

1. Set $S = \{1, \dots, 100n\}$.
2. Choose a_1, \dots, a_n randomly from S with replacement
3. Evaluate $\det(a_1, \dots, a_n)$. If this equals 0, then *accept*. Otherwise, *reject*.

Then A accepts $\langle L \rangle$ with probability 1 when $\det L = 0$. Also, it rejects with probability $\geq \frac{99}{100}$ when $\det L \neq 0$ because

$$\mathbb{P}[\det(a_1, \dots, a_n) = 0] \leq \frac{1}{100}.$$

Since evaluating a polynomial is polynomial in its degree, we see that A is polynomial in n .

3.11 Lecture 19

Example 3.11.1. Let $G = (V_1, V_2, E)$ be a bipartite graph with $|V_1| = |V_2| = n$. A *perfect matching* is a permutation σ of $\{1, 2, \dots, n\}$ such that $(i, \sigma(i)) \in E$ for each $i = 1, \dots, n$.

Consider the $n \times n$ matrix $M := (m_{i,j})$ defined by

$$m_{i,j} \equiv \begin{cases} X_{ij} & (i, j) \in E \\ 0 & (i, j) \notin E \end{cases}.$$

Since

$$\det M = \sum_{\sigma \in S_n} (-1)^{\text{sgn } \sigma} \prod_{i=1}^n m_{i, \sigma(i)},$$

we see that $\det M \neq 0$ if and only if G has a perfect matching. By Example 3.10.8, it follows that deciding whether or not a finite graph has a perfect matching belongs to **BPP**.

Let X_1, \dots, X_n be independent Boolean-valued random variables. Suppose that $\mathbb{E}[X_i] = \mathbb{E}[X_1]$ for every $1 \leq i \leq n$. Let $\mu = \mathbb{E}[X_1]$ and $Z = \frac{X_1 + \dots + X_n}{n}$, so that $\mathbb{E}[Z] = \mu$.

Theorem 3.11.2 (Chernoff bound). *For all $t \in (0, 1)$,*

$$\mathbb{P}[|Z - \mu| \geq t] \leq e^{-\frac{t^2 n \mu}{4}}.$$

Corollary 3.11.3. *Let M be a randomized polynomial time TM and let $L \subset \Sigma^*$. Suppose that there exists $c > 0$ such that*

- *for any $x \in L$, $\mathbb{P}_{r \in_R \{0,1\}^{\text{poly}(|x|)}} [M(x,r) = 1] \geq \frac{1}{2} + n^{-c}$ and*
- *for any $x \notin L$, $\mathbb{P}_{r \in_R \{0,1\}^{\text{poly}(|x|)}} [M(x,r) = 0] \geq \frac{1}{2} + n^{-c}$*

where n denotes $|x|$. Then for any $c' > 0$, there exist a randomized polynomial time TM M' such that

- *for any $x \in L$, $\mathbb{P}_{r \in_R \{0,1\}^{\text{poly}(|x|)}} [M'(x,r) = 1] \geq 1 - 2^{-n^{c'}}$ and*
- *for any $x \notin L$, $\mathbb{P}_{r \in_R \{0,1\}^{\text{poly}(|x|)}} [M'(x,r) = 0] \geq 1 - 2^{-n^{c'}}$.*

Proof. Let $m = n^{2c+2c'+100}$. Define M' as follows. On any input x , run $M(x)$ m times, with outputs y_1, \dots, y_m . Accept if M accepts x more than $\frac{m}{2}$ times and reject otherwise.

For each $i \in \{1, \dots, m\}$, define the random variable

$$X_i = \begin{cases} 1 & y_i = \chi_L(x) \\ 0 & \text{otherwise} \end{cases}.$$

Then $\mathbb{E}[X_i] = \mathbb{P}[X_i = 1] \geq \mu := \frac{1}{2} + n^{-c}$. We can use Theorem 3.11.2 to get

$$\begin{aligned} \mathbb{P}\left[\sum_{i=1}^m X_i \leq \frac{m}{2}\right] &\leq \mathbb{P}\left[\left|\frac{\sum_{i=1}^m X_i}{m} - \mu\right| \geq n^{-c}\right] \\ &\leq e^{-\frac{n^{-2c}(n^{2c+2c'+100})(\frac{1}{2}+n^{-c})}{4}} \\ &= \frac{1}{e^{\frac{n^{2c'+100}(\frac{1}{2}+n^{-c})}{4}}} \\ &= \frac{1}{e^{\frac{n^{2c'+100}}{8} + \frac{n^{2c'-c+100}}{4}}} \\ &= \frac{1}{e^{\frac{n^{2c'+100}+2n^{2c'-c+100}}{8}}} \\ &\leq \frac{1}{e^{\frac{1}{8}n^{2c'+100}}} \\ &\leq \frac{1}{2^{n^{c'}}}. \end{aligned}$$

□

Note 3.11.4. Call a random bit r *bad for x* if $M(x,r) \neq \chi_L(x)$ and *good for x* otherwise. For any x of length n , we have that $\mathbb{P}_{r \in_R \{0,1\}^{\text{poly}(|x|)}} [r \text{ is bad for } x] \leq 2^{-n^c}$. Thus,

$$\mathbb{P}_{r \in_R \{0,1\}^{\text{poly}(|x|)}} [r \text{ is bad for some } x \text{ of length } n] \leq 2^{-n^c} \cdot 2^n \ll 2^{-n}$$

when c is large, and

$$\mathbb{P}_{r \in_R \{0,1\}^{\text{poly}(|x|)}} [r \text{ is good for every } x \text{ of length } n] \geq 1 - 2^{-n}.$$

Definition 3.11.5.

1. Let **RP** consist of those languages L for which there is an efficient randomized TM M such that

- for any $x \in L$, $\mathbb{P}_{r \in_R \{0,1\}^{t(|x|)}} [M(x, r) = 1] \geq \frac{2}{3}$ and
- for any $x \notin L$, $\mathbb{P}_{r \in_R \{0,1\}^{t(|x|)}} [M(x, r) = 0] = 1$

where $t(n)$ denotes the time complexity of M .

2. Let **co-RP** consist of those languages L for which there is an efficient randomized TM M such that

- for any $x \in L$, $\mathbb{P}_{r \in_R \{0,1\}^{t(|x|)}} [M(x, r) = 1] = 1$ and
- for any $x \notin L$, $\mathbb{P}_{r \in_R \{0,1\}^{t(|x|)}} [M(x, r) = 0] \geq \frac{2}{3}$

where $t(n)$ denotes the time complexity of M .

3. Let **ZPP** = **RP** \cap **co-RP**.

We have that $L \in \mathbf{ZPP}$ if there exists a randomized algorithm that runs in expected polynomial time and never errs.

3.12 Lecture 20

Theorem 3.12.1. *If there exist $L \in \text{DTIME}(2^{O(n)})$ and $\gamma > 0$ such that L requires circuits of size at least $2^{\gamma n}$, then $\mathbf{P} = \mathbf{BPP}$.*

Recall that any algorithm running in time $t(n)$ can be simulated by circuits of size $t(n)^2$. Let

$$L = \{1^n \mid n \in \mathbb{N}, \text{ the TM represented by the number } n \text{ in binary halts when its input equals } n\}.$$

Then L is undecidable but has polynomial size circuits.

Theorem 3.12.2 (Adleman). *Every $L \in \mathbf{BPP}$ has polynomial size circuits. In other words,*

$$\mathbf{BPP} \subset \mathbf{P}/\text{poly}.$$

Proof. Let $L(M) = L$ where M is a randomized TM that runs in polynomial time. For every $n \in \mathbb{N}$, Note 3.11.4 implies that there is some random bit r_n such that for any string x of size n , $M(x, r_n) = \chi_L(x)$. From this we can obtain a circuit C_{r_n} of size quadratic in the running time of M such that

$$C_{r_n}(x) = M(x, r_n) = \chi_L(x)$$

for each x of size n . □

Corollary 3.12.3. **BPP** \subset **EXP**.

Definition 3.12.4 (Polynomial hierarchy).

1. For any $i \in \mathbb{N}$, Σ_p^i is the class of languages L for which there exist a polynomial time computable predicate P and polynomials $p_1(\cdot), \dots, p_i(\cdot)$ such that

$$x \in L \iff \exists \bar{x}_1 \in \{0,1\}^{p_1(|x|)} \forall \bar{x}_2 \in \{0,1\}^{p_2(|x|)} \dots \exists \forall \bar{x}_i \in \{0,1\}^{p_i(|x|)} (P(x, \bar{x}_1, \dots, \bar{x}_i) = 1).$$

2. For any $i \in \mathbb{N}$, Π_p^i is the class of languages L for which there exists a polynomial time computable predicate P and polynomials $p_1(\cdot), \dots, p_i(\cdot)$ such that

$$x \in L \iff \forall \bar{x}_1 \in \{0, 1\}^{p_1(|x|)} \exists \bar{x}_2 \in \{0, 1\}^{p_2(|x|)} \dots \exists / \forall \bar{x}_i \in \{0, 1\}^{p_i(|x|)} (P(x, \bar{x}_1, \dots, \bar{x}_i) = 1).$$

The *polynomial hierarchy* is the set of languages $\mathbf{PH} := \bigcup_{i \in \mathbb{N}} \Sigma_p^i$.

Aside. For a given (finite) *vocabulary* σ , let $\text{STRUC}[\sigma]$ denote the set of all finite structures of σ equipped with a total ordering. Consider the set

$$\mathcal{B} := \{I_b \mid I_b : \text{STRUC}[\sigma] \rightarrow \{0, 1\}, \sigma \text{ is a vocabulary}\}.$$

For each function $I_b : \text{STRUC}[\sigma] \rightarrow \{0, 1\}$, let

$$\mathcal{L}_{I_b} = \{A \in \text{STRUC}[\sigma] \mid I_b(A) = 1\},$$

called a *Boolean query*. Consider the set $\mathcal{B} := \{\mathcal{L}_{I_b} \mid I_b \in \mathcal{B}\}$ of all Boolean queries. Let \mathbf{SO} denote the set of all Boolean queries expressible in second-order logic. That is, $\mathcal{L}_{I_b} \in \mathbf{SO}$ iff there is some second-order sentence φ such that

$$I_b(A) = 1 \iff A \models \varphi.$$

It is known that $\mathbf{SO} = \mathbf{PH}$. This is a well-known result of so-called *descriptive complexity theory*, a branch of finite model theory.

Example 3.12.5. We see that $\text{MAX-CLIQUE} \in \Sigma_p^2$ because it is defined by the formula “there exists a choice of vertices V_1 such that for any choice of vertices V_2 , V_1 is a clique of size k and V_2 is either not a clique or of size smaller than k .”

3.13 Lecture 21

Note 3.13.1.

1. $\Sigma_p^0 = \mathbf{P}$.
2. $\Sigma_p^1 = \mathbf{NP}$.
3. $\Sigma_p^k \subset \Sigma_p^{k+1} \cap \Pi_p^{k+1}$.
4. $\Pi_p^k \subset \Sigma_p^{k+1} \cap \Pi_p^{k+1}$.
5. $\text{co-}\Sigma_p^k = \Pi_p^k$.

Lemma 3.13.2. *If $k > 0$ and $\Sigma_p^k = \Pi_p^k$, then $\Sigma_p^{k+1} = \Sigma_p^k$.*

Proof. For simplicity, let $k = 1$. Note that $L \in \Sigma_p^2$ if and only if some formula

$$\varphi(x) := \exists \bar{y}_1 \forall \bar{y}_2 (P(x, \bar{y}_1, \bar{y}_2))$$

defines L . But, by assumption, $\varphi(x)$ is equivalent to some formula $\exists \bar{y}_1 \exists \bar{y}_2 (P'(x, \bar{y}_1, \bar{y}_2))$. □

Theorem 3.13.3 (Sipser-Gács). $\mathbf{BPP} \subset \Sigma_p^2 \cap \Pi_p^2$.

Proof. Since $\mathbf{BPP} = \text{co-BPP}$, it suffices to show that $\mathbf{BPP} \subset \Sigma_p^2$. If $L \in \mathbf{BPP}$, then there exists an efficient algorithm A such that $\mathbb{P}_{r \in_R \{0,1\}^{\text{poly}(n)}} [A(x, r) = \chi_L(x)] \geq \frac{2}{3}$ where n denotes $|x|$. Define A' to run $A(x, r_1), \dots, A(x, r_s)$ and take the majority. Then A' uses st random bits, and

$$\mathbb{P}_{r_1, \dots, r_s} [A'(x, r_1, \dots, r_s) = \chi_L(x)] \geq 1 - 2^{-s(n)}.$$

By choosing $s \gg 10t^2$, we see that $\mathbb{P}[A'(x, \bar{r}) = \chi_L(x)] \geq 1 - \frac{1}{100m^2}$ where m denotes the number of random bits used.

Claim. $x \in L \iff \exists \bar{y}_1, \dots, \bar{y}_m \in \{0, 1\}^m \forall \bar{z} \in \{0, 1\}^m \bigvee_{j=1}^m A'(x, \bar{y}_j \oplus \bar{z}) = 1$.

Proof.

(\implies)

Suppose that $x \in L$. It suffices to show that

$$\mathbb{P}_{\bar{y}_1, \dots, \bar{y}_m} \left[\exists \bar{z} \in \{0, 1\}^m \bigwedge_{j=1}^m A'(\bar{x}, \bar{y}_j \oplus \bar{z}) \neq 1 \right] < 1.$$

Note that $\mathbb{P}_{\bar{y}_1, \dots, \bar{y}_m} \left[\bigwedge_{j=1}^m A'(\bar{x}, \bar{y}_j \oplus \bar{z}) \neq 1 \right] \leq \frac{1}{(100m^2)^m}$ for any $\bar{z} \in \{0, 1\}^m$. Therefore,

$$\mathbb{P}_{\bar{y}_1, \dots, \bar{y}_m} \left[\exists \bar{z} \in \{0, 1\}^m \bigwedge_{j=1}^m A'(\bar{x}, \bar{y}_j \oplus \bar{z}) \neq 1 \right] \leq \frac{2^m}{(100m^2)^m} < 1.$$

(\impliedby)

Suppose that $x \notin L$. Fix y_1, \dots, y_m . Note that $\mathbb{P}_{z \in_R \{0,1\}^*} [A(x, y_j \oplus z) = 1] \leq \frac{1}{100m^2}$ for each $j = 1, \dots, m$. This implies that

$$\mathbb{P}_{z \in_R \{0,1\}^*} \left[\bigvee_{j=1}^m A(x, y_j \oplus z) = 1 \right] \leq \frac{1}{100m^2} \leq \frac{m}{100m^2} = \frac{1}{100m} < 1.$$

□

This completes our proof. □

3.14 Lecture 22

Definition 3.14.1 (Interactive protocol).

1. Let $V, P : \{0, 1\}^* \rightarrow \{0, 1\}^*$ be mappings. Let x be a binary string and $r \in_R \{0, 1\}^*$. A k -round (randomized) interaction of V and P on x and r is the sequence of length k consisting of the following strings.

$$\begin{aligned} a_1 &= V(x, r) \\ a_2 &= P(x, a_1) \\ &\vdots \\ a_{2i+1} &= V(x, r, a_1, \dots, a_{2i}) \\ a_{2i+2} &= P(x, a_1, \dots, a_{2i+1}) \end{aligned}$$

Let $\text{out}_{\langle V, P \rangle}(x, r)$ denote the final string of this sequence. We call V a *verifier* and P a *prover*.

2. Let $k : \mathbb{N} \rightarrow \mathbb{N}$ be polynomial computable. A language L has a *has a k -round (randomized) interactive protocol* or *lies in the class $\mathbf{IP}[k]$* if there exists a randomized TM V that V is polynomial in its first input and

(a) (completeness) if $x \in L$, then there exists a prover P such that $\langle V, P \rangle(x)$ is a $k(|x|)$ -round interaction with

$$\mathbb{P}_{r \in R \in \{0,1\}^{\text{poly}(|x|)}} [\text{out}_{\langle V, P \rangle}(x, r) = 1] \geq \frac{2}{3}$$

and

(b) (soundness) if $x \notin L$, then for any prover P such that $\langle V, P \rangle(x)$ is a $k(|x|)$ -round interaction,

$$\mathbb{P}_{r \in R \in \{0,1\}^{\text{poly}(|x|)}} [\text{out}_{\langle V, P \rangle}(x, r) = 1] \leq \frac{1}{3}.$$

3. Let $\mathbf{IP} = \bigcup_{k \in \mathbb{N}} \mathbf{IP}[n^k]$.

Recall that two graphs (V, E) and (V', E') are *isomorphic* if there is a bijection $f : V \rightarrow V'$ such that $(x, y) \in E \iff (f(x), f(y)) \in E'$.

Example 3.14.2. Let $\mathbf{NIP} = \{\langle G_1, G_2 \rangle \mid G_1 \text{ and } G_2 \text{ are non-isomorphic graphs}\}$. The following interaction shows that $\mathbf{NIP} \in \mathbf{IP}$.

V : Pick $i \in \{1, 2\}$ uniformly randomly. Randomly permute the vertices of G_i to get a new isomorphic graph H .
Send H to P .

P : If H is not isomorphic to one of G_1 and G_2 , then select the other graph.

Otherwise, select one of G_1 and G_2 by flipping a coin. Let G_j denote the selected graph. Send j to V .

V : Pick $i' \in \{1, 2\}$ uniformly randomly. Randomly permute the vertices of $G_{i'}$ to get a new isomorphic graph H' .
Send H' to P .

P : If H' is not isomorphic to one of G_1 and G_2 , then select the other graph.

Otherwise, select one of G_1 and G_2 by flipping a coin. Let $G_{j'}$ denote the selected graph. Send j' to V .

V : Accept if $i = j$ and $i' = j'$. Reject otherwise.

3.15 Lecture 23

Proposition 3.15.1. \mathbf{IP} is closed under complementation.

Remark 3.15.2. The prover P of a k -round interaction can be assumed, without loss of generality, to decide languages in and only in PSPACE. As a result, $\mathbf{IP} \subset \text{PSPACE}$.

Theorem 3.15.3. $\text{PSPACE} \subset \mathbf{IP}$.

Corollary 3.15.4. $\text{PSPACE} = \mathbf{IP}$.

Definition 3.15.5 (Hash function). Let A and B be sets of size 2^n and 2^k , respectively. A set of functions $\mathcal{H} := \{h_1, \dots, h_t\}$ from A to B is *pairwise independent* if for any distinct $x, x' \in A$ and any $y, y' \in B$,

$$\mathbb{P}_{h \in_R \mathcal{H}} [h(x) = y \wedge h(x') = y'] = \frac{1}{2^{2k}} = \frac{1}{|B|^2}.$$

An element of such a set is called a (*pairwise independent*) *hash function*.

Example 3.15.6.

1. The set of all functions $A \rightarrow B$ is a pairwise independent set of size $|B|^{|A|}$.
2. Let $q = 2^n$. For each $(s, t) \in \mathbb{F}_q \times \mathbb{F}_q$, define $h_{s,t} : \mathbb{F}_q \rightarrow \mathbb{F}_q$ by $h_{s,t}(a) = a \cdot s + t$. If $x, y, x', y' \in \mathbb{F}_q$ with $x \neq x'$, then the system of equations

$$\begin{aligned} sx + t &= y \\ sx' + t &= y' \end{aligned}$$

is satisfied $\iff \begin{bmatrix} x & 1 \\ x' & 1 \end{bmatrix} \begin{bmatrix} s \\ t \end{bmatrix} = \begin{bmatrix} y \\ y' \end{bmatrix} \iff \begin{bmatrix} x & 1 \\ x' & 1 \end{bmatrix}^{-1} \begin{bmatrix} y \\ y' \end{bmatrix} = \begin{bmatrix} s \\ t \end{bmatrix}$. Therefore,

$$\mathbb{P}_{(s,t) \in \mathbb{R}\mathbb{F}_q \times \mathbb{F}_q} [h_{s,t}(x) = y \wedge h_{s,t}(x') = y'] = \frac{1}{q^2},$$

which proves that $h_{s,t}$ is a hash function.

3.16 Lecture 24

Proposition 3.16.1. *Let G and H be graphs.*

1. If $G \not\cong H$, then $\text{Aut}(G \cup H) \cong \text{Aut}(G) \times \text{Aut}(H)$.
2. There is some $k \in \mathbb{N}$ such that

(a) $|\text{Aut}(G \cup H)| \geq 2k$ whenever $G \cong H$ and

(b) $|\text{Aut}(G \cup H)| \leq k$ whenever $G \not\cong H$.

Example 3.16.2 (Goldwasser-Sipser set bound protocol). Let $S \subset \{0, 1\}^m$ and $K \in \mathbb{N}$. We want to construct a verifier V and prover P such that

- V can efficiently check whether any given x belongs to S and
- it is guaranteed that either $|S| \leq \frac{K}{2}$ or $|S| \geq K$.

To do this, choose $l \in \mathbb{N}$ such that $2^{l-2} \leq K \leq 2^{l-1}$ and $|S| \leq 2^{l-1}$. Let \mathcal{H} denote a pairwise independent set of mappings $\{0, 1\}^m \rightarrow \{0, 1\}^l$.

Have V randomly choose $h \in \mathcal{H}$ and $y \in \{0, 1\}^l$ and then send (h, y) to P . Next, have P send $x \in_{\mathbb{R}} \{0, 1\}^m$ to V . Finally, have V accept if and only if $x \in S$ and $h(x) = y$.

Case 1: Suppose that $|S| \leq \frac{K}{2}$.

If $x \in S$, then $\mathbb{P}_{h \in_{\mathbb{R}} \mathcal{H}} [h(x) = y] = \frac{1}{2^l}$. Moreover, if p denotes the quantity $\frac{|K|}{2^l}$, then

$$\mathbb{P}_{h \in_{\mathbb{R}} \mathcal{H}} [(\exists x \in S) (h(x) = y)] \leq \frac{|S|}{2^l} \leq \frac{|K|}{2 \cdot 2^l} = \frac{p}{2}.$$

Case 2: Suppose that $|S| \geq K$.

We compute

$$\begin{aligned}
\mathbb{P}_{h \in \mathcal{H}}[(\exists x \in S)(h(x) = y)] &\geq \sum_{x \in S} \mathbb{P}[h(x) = y] - \sum_{\substack{x, x' \in S \\ x \neq x'}} \mathbb{P}[h(x) = y \wedge h(x') = y] \\
&\geq \frac{|S|}{2^l} - \underbrace{\frac{|S|(|S| - 1)}{2}}_{\binom{|S|}{2}} \cdot \frac{1}{2^{2l}} \\
&= \frac{|S|}{2^l} \left(1 - \frac{|S| - 1}{2} \cdot \frac{1}{2^l}\right) \\
&\geq \frac{|S|}{2^l} \left(1 - \frac{|S|}{2 \cdot 2^l}\right) \\
&\geq \frac{K}{2^l} \left(1 - \frac{|S|}{2 \cdot 2^l}\right) \\
&\geq \frac{3}{4} \cdot p.
\end{aligned}$$

3.17 Lecture 25

Let $n \in \mathbb{N}$ and choose a prime $2^{10n} \leq p \leq 2^{20n}$. Let $\varphi(x_1, \dots, x_n)$ be a 3cnf formula with m clauses and let $\tilde{\varphi}(x_1, \dots, x_n)$ be the polynomial obtained from φ by the following translation rules.

- $\bar{x} \longleftrightarrow (1 - x)$.
- $x \wedge y \longleftrightarrow x \cdot y$.

For any $a_1, \dots, a_i \in \mathbb{Z}_p$, define

$$S(a_1, \dots, a_i) = \sum_{x \in \{0,1\}^{n-i}} \tilde{\varphi}(a_1, \dots, a_i, x) \pmod{p}.$$

Lemma 3.17.1 (Sum-check protocol). *For any $K \in \mathbb{N}$, there exists an efficient interactive protocol (V, P) such that*

- if $K = S(a_1, \dots, a_i)$, then V accepts $\langle \varphi, p \rangle$ with probability 1 and
- if $K \neq S(a_1, \dots, a_i)$, then V rejects $\langle \varphi, p \rangle$ with probability $\geq \left(1 - \frac{d}{p}\right)^{n-i}$ where $d \equiv 3m \leq n^3$.

3.18 Lecture 26

Proof. First, we construct (V, P) as follows.

1. \underline{V} : If $n = 1$, then compute $\tilde{\varphi}(0) + \tilde{\varphi}(1)$. If this equals K , then *accept*. Otherwise, *reject*.

If $n > 1$, then let

$$h_1(x_1) = \sum_{x_2, \dots, x_n \in \{0,1\}} \tilde{\varphi}(x_1, x_2, \dots, x_n),$$

which is a univariate polynomial of degree at most n^3 . Ask P to send $h_1(x_1)$.

2. \underline{P} : Return $h'_1(x_1)$ to V where $h'_1(x_1)$ is univariate and has degree at most d .
3. \underline{V} : Compute $h'_1(0) + h'_1(1)$. If this equals K , then *reject*.

Otherwise, choose $a_1 \in_R \mathbb{F}_p$. Recursively run the same protocol thus far with K replaced with $h'_1(a_1)$ and $\sum_{x_1 \in \{0,1\}} \cdots \sum_{x_n \in \{0,1\}} \tilde{\varphi}(x_1, x_2, \dots, x_n)$ replaced with

$$\sum_{x_2 \in \{0,1\}} \cdots \sum_{x_n \in \{0,1\}} \tilde{\varphi}(a_1, x_2, \dots, x_n).$$

Next, we must verify the correctness of (V, P) . If $K = \sum_{x_1, \dots, x_n \in \{0,1\}} \tilde{\varphi}(x_1, \dots, x_n)$, then have P return $h_i(x_i)$ for each $i = 1, \dots, n-1$. In this case, V accepts with probability 1.

Now, assume that $K \neq \sum_{x_1, \dots, x_n \in \{0,1\}} \tilde{\varphi}(x_1, \dots, x_n)$. If $n = 1$, then clearly V rejects with probability 1. Assume, inductively, that V rejects with high probability for any polynomial of degree $\leq d$ in $n-1$ variables. If $h'_1(x_1) = h_1(x_1)$, then V rejects with probability 1. Assume that $h'_1(x_1) \neq h_1(x_1)$. Note that the polynomial $h'_1 - h_1$ is nonzero and has degree at most d . By Lemma 3.10.7, it follows that

$$\mathbb{P}_{a \in_R \mathbb{F}_p} [h'_1(a) \neq h_1(a)] \geq 1 - \frac{d}{p}.$$

Since $s(a) \neq h(a) = \sum_{x_2 \in \{0,1\}} \cdots \sum_{x_n \in \{0,1\}} \tilde{\varphi}(a_1, x_2, \dots, x_n)$, we see, by our induction hypothesis, that V rejects its recursive input with probability $\geq (1 - \frac{d}{p})^{n-1}$. Thus, V rejects (φ, K, p) with probability

$$\geq \left(1 - \frac{d}{p}\right)^{n-1} \left(1 - \frac{d}{p}\right) = \left(1 - \frac{d}{p}\right)^n,$$

as desired. □

Proposition 3.18.1. *The language of all unsatisfiable 3cnf formulas is **co-NP**-complete.*

Corollary 3.18.2. **co-NP** \subset **IP**.

Proof. We can modify our interactive protocol in Lemma 3.17.1 so that its first round has P send a large enough prime p to V . As a result, we can remove p from the input of (V, P) . Notice that φ is unsatisfiable if and only if $\sum_{x \in \{0,1\}^n} \tilde{\varphi}(x_1, \dots, x_n) = 0$. This, in turn, is true if and only if

$$\sum_{x \in \{0,1\}^n} \tilde{\varphi}(x_1, \dots, x_n) = 0 \pmod{p}$$

since $0 \leq \sum_{x \in \{0,1\}^n} \tilde{\varphi}(x_1, \dots, x_n) \leq 2^n$. Thanks to Proposition 3.18.1, we are done. □

Theorem 3.18.3. **IP** = **PSPACE**.

3.19 Final exam review session

Theorem 3.19.1 (Space hierarchy). *If $f : \mathbb{N} \rightarrow \mathbb{N}$ satisfies $f(n) \geq \log n$, then $\text{DSPACE}(f(n)) \subsetneq \text{DSPACE}(f^2(n))$.*

Example 3.19.2. Since $\log^2(n) \leq p(n)$ for some polynomial $p : \mathbb{N} \rightarrow \mathbb{N}$, the space hierarchy theorem implies that **L** \subsetneq **PSPACE**.
